Allergy Shots

50 Million Americans
Suffer From Allergies

Allergy shots are

over 90% effective

in reducing allergy symptoms*

Allergy Shots (Immunotherapy) is a treatment used to relieve allergy symptoms of heavy fever (itchy eyes/nose, congestion, runny nose, sneezing) or allergic asthma (chronic cough or wheeze) by administering injections of substances such as pollen, mold spores, dust mites, animal dander or insects to which an individual has been found to be allergic to by skin testing.

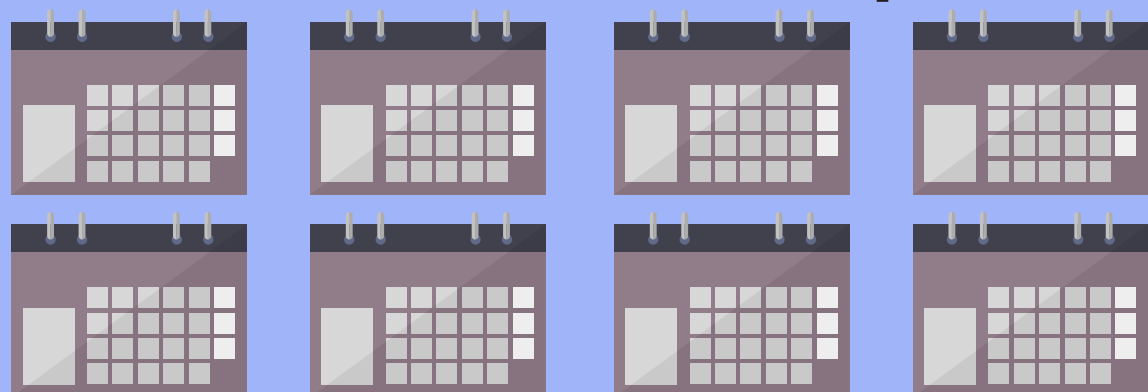

What are allergy Shots?

It is a process of desensitization over a period of time.

Although it requires time and patience, the payback can be long-term, medication-free relief.

The Two Phase Process

6-9 Months: Build-Up Phase

We give increasing doses of allergy injections once or twice a week until a predetermined target or "maintenance" dose is achieved.

Most patients will see a clinical improvement with immunotherapy within the 1st year.

Immunotherapy can lead up to 10 years of being symptom free from allergies.

1 Year:

3-5 Years: Maintenance Phase

Allergies are increasing. They affect as many as 30% of adults and 40% of children in the United States.

Allergy Symptoms

- Itchy and watery eyes
